PC/AT®-COMPATIBLE UART FAMILY

FAMILY FEATURES

- IBM PC/AT-compatible
- Individual modem control signals for each channel
- Programmable serial interface characteristics for each channel:
 - 5-, 6-, 7- or 8-bit characters
 - Even-, odd- or no-parity bit generation and detection
 - 1, 1-1/2, or 2 stop bit generation
- Independent control of transmit, receive, line status and data set interrupts on each channel
- Three-state TTL drive for the data and control bus on each channel

FAMILY DESCRIPTION

The universal asynchronous receiver/transmitter (UART) serves as serial input/output interfaces in microcomputer- or microprocessor-based systems.

It performs serial-to-parallel conversion on data characters received from peripheral devices or modems, and parallel-to-serial conversion on data characters transmitted by the CPU. The complete status of each channel of the UART can be read at any time during functional operation by the CPU. The information obtained includes the type and condition of the transfer operations being performed and error conditions.

Four UARTs provide the user with a fully bidirectional parallel data port that fully supports the parallel Centronics type printer. The parallel port, together with the serial port(s), provide IBM PC/AT-compatible computers with a single device to serve the system port(s).

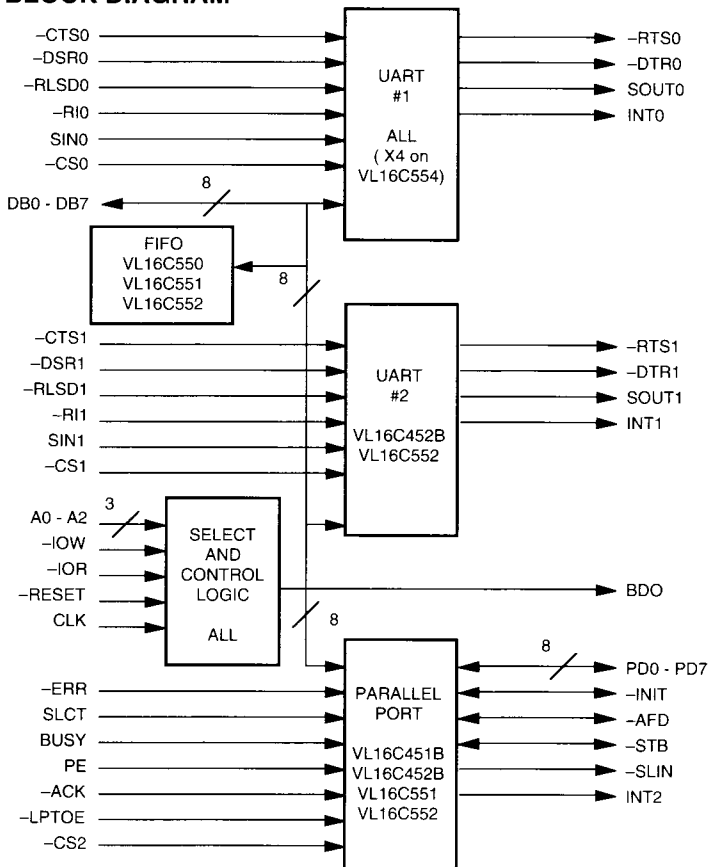

A programmable baud rate generator is included that can divide the timing reference clock input by a divisor between 1 and $(2^{16}-1)$.

The VLSI family of UARTs is housed in 40-lead plastic DIPs, 44-lead PLCCs, 68-lead PLCCs, and 84-lead quad PLCCs.
