

- **486DX Architecture and Performance**
 - 486-Compatible Instruction Set and Register Set
 - Integrated Floating-Point Unit (FPU)
 - Integrated 16-Bit Hardware Multiplier
 - On-Chip 8K-Byte, 32-Bit Instruction/Data Cache Can be Configured to Operate in Write-Through or Write-Back Mode
 - Clock-Tripled Operation at 3.45-V With 5-V-Tolerant I/Os
 - Highly Optimized, Variable-Length Pipeline
- **High-Performance, Footprint-Compatible Upgrade for 486-Class Platforms**
 - Drop-in Replacement for Existing TI486DX2 Microprocessors
 - Internal CPU Clock Speeds of 100 MHz
 - Industry-Standard Footprints Using 168-Pin Ceramic PGA and 208-Pin Ceramic QFP
- **Advanced Power-Management Features for Battery-Powered Notebook and Energy-Efficient Desktop PC Systems**
 - System-Management Mode (SMM)
 - High-Priority System-Management Interrupt (SMI) With Separate Memory-Address Space
 - Suspend Mode (Initiated by Hardware or Software)
 - Fully Static Device Permits Clock-Stop State
 - 3.45-V Device With 5-V-Tolerant I/Os Can Be Used in 3.45-V-Only or Mixed 3.45-V/5-V Systems
- **Architecture Features 32-Bit Internal and 32-Bit External Buses.**
- **Fabricated Using the Texas Instruments (TI™) EPIC™ Submicron CMOS Technology**

description

The TI486DX4 microprocessors are attractive for new 486-compatible system designs because they are instruction-set and footprint compatible with 486-class platforms. They feature an on-chip floating point unit (FPU), 8K-byte cache, clock-tripled CPU, and advanced power-management techniques. The devices operate from a 3.45-V power supply in 3.45-V-only systems or mixed 3.45-V/5-V systems. An industry-standard footprint facilitates implementation of energy-efficient desktop and/or battery-powered notebook systems.

The TI486DX4 microprocessors support 8-, 16-, and 32-bit data types and operate in real, virtual-8086, and protected modes. The microprocessors achieve high performance through use of a highly optimized, variable-length pipeline combined with a RISC-like, single-cycle execution unit, an integrated floating point unit, a hardware multiplier, and an 8K-byte integrated instruction and data cache. The microprocessor can access up to 4G bytes of physical memory using a 32-bit bus and can perform bus cycles in burst mode to improve the efficiency of multiple word transfers.

description (continued)

The TI486DX4 microprocessors are ideal for battery-powered applications because they typically draw 500 μ A when the input clock is stopped in the suspend mode.

The TI486DX4 microprocessors contain an on-chip 8K-byte cache memory that can be configured to operate in write-through or write-back mode. Conventional write-through mode updates external memory for each cache transaction. The write-back mode permits cache transactions to occur without updating external memory until a cache miss occurs, a modified line is replaced in the cache, or when an external bus master requires access to data. Configuring the cache to operate in write-back mode can improve overall performance by up to 15% when compared to write-through mode.

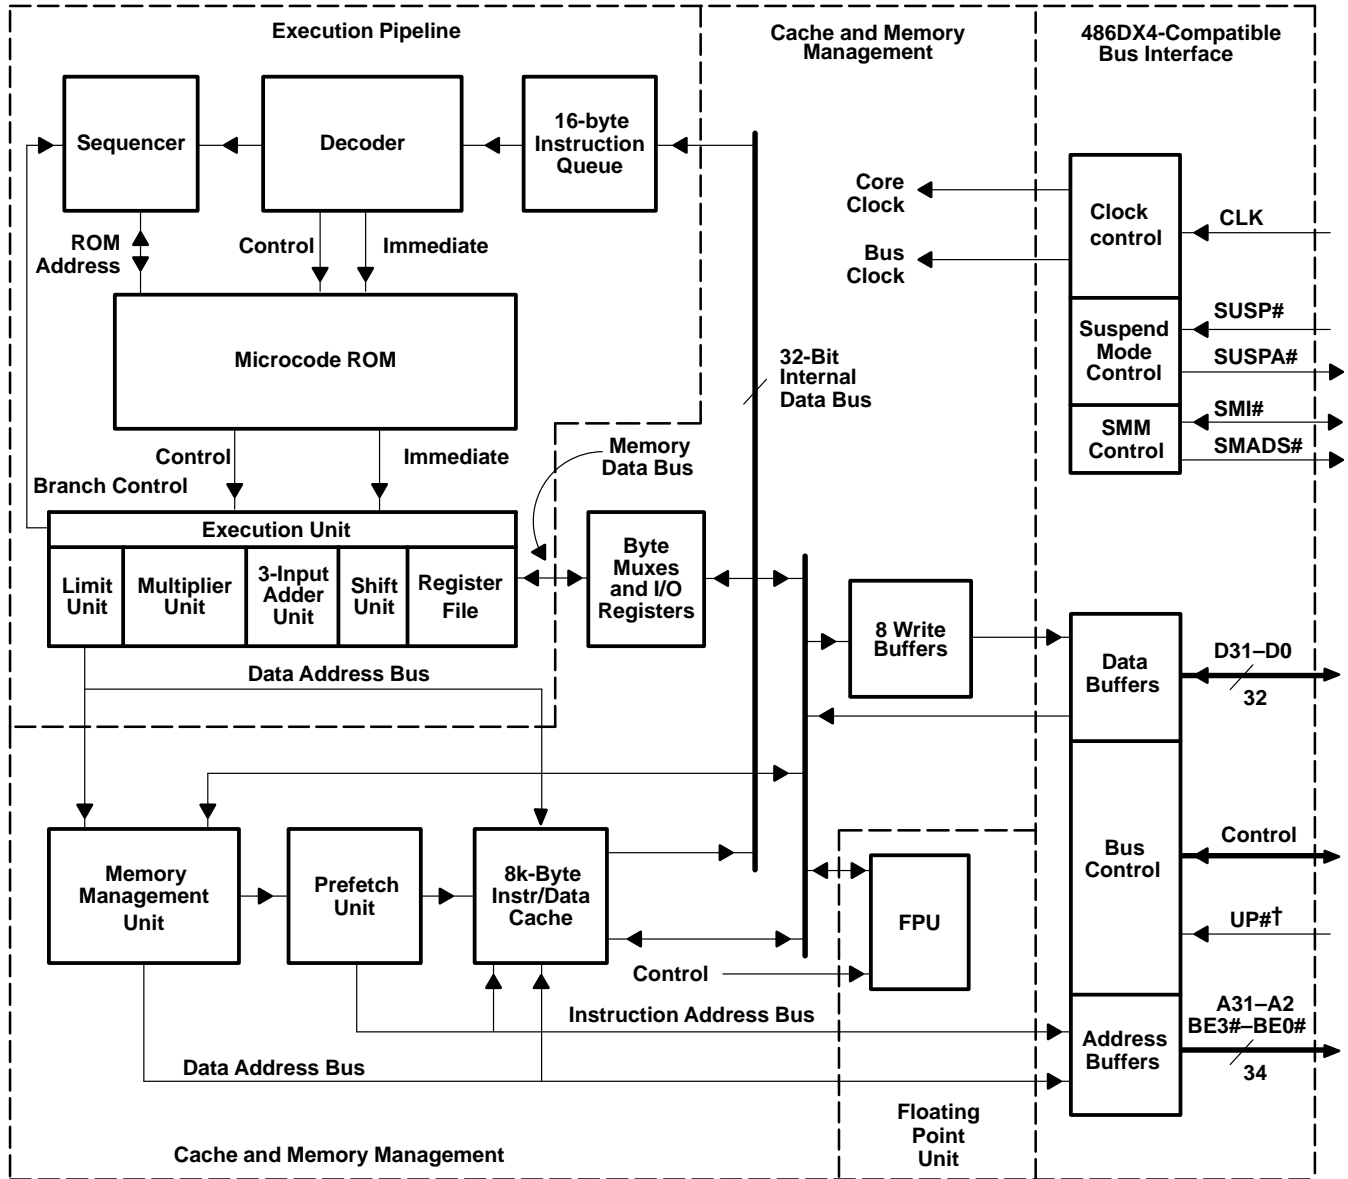

The TI486DX4 microprocessors are fabricated using the Texas Instruments EPIC submicron CMOS technology. The combination of high-performance 486 operation, on-chip FPU, internal 8K-byte cache, 32-bit external data path, and advanced power-management features makes the TI486DX4 well suited for energy-efficient desktop and notebook applications.

terminal assignments

The terminal assignments for the 168-pin, CPGA TI486DX4 microprocessors are shown as viewed from the terminal side (bottom) in Figure 1. The signal names are listed in Table 1 and Table 2 sorted by terminal number and signal name, respectively.

Figure 1. 168-Pin CPGA Terminal Assignments

NC — Make no external connection

NOTE A: Connecting or terminating (high or low) any NC terminal(s) may cause unpredictable results or nonperformance of the microprocessor.

Terminal Functions

TERMINAL NAME	TERMINAL NO.		DESCRIPTION
	168-PIN	208-PIN	
A2	Q14	202	Address Bus (active high). The address bus (A31–A2) signals provide addresses for physical memory and I/O ports. Address lines A31–A4 are bidirectional signals used by the TI486DX4 to drive addresses to memory and I/O devices and are also used by the system logic to drive cache inquiry addresses into the processor. Address lines A3–A2 are output signals only and are ignored during cache inquiry cycles. All address lines can be used for addressing physical memory allowing a 4G-byte address space (0000 0000h to FFFF FFFFh). During I/O port accesses, A31–A16 are driven low (except for coprocessor accesses). This permits a 64-Kbyte I/O address space (0000 0000h to 0000 FFFFh).

A30	P3	148	
A31	Q1	147	
ADS#	S17	203	
AHOLD	A17	17	Address Hold Request (active high). This input forces the microprocessor to float A31–2 in the next clock cycle. While AHOLD is asserted, only the address bus is disabled. The current bus cycle remains active and completes in the normal fashion. No additional bus cycles are generated while AHOLD is asserted, except cache line write-back cycles in response to a cache inquiry. The microprocessor samples AHOLD during RESET. If AHOLD is asserted at the clock edge prior to the falling edge of RESET, built-in self test is executed prior to issuing any bus cycles. AHOLD is internally connected to a pulldown resistor to prevent it from floating active when left unconnected.

Terminal Functions (continued)

TERMINAL NAME NO. 168-PIN 208-PIN	DESCRIPTION
A20M# D15 47	<p>Address Bit-20 Mask (active low). This input causes the microprocessor to mask (force low) physical address bit 20 when driving the external address bus or performing an internal cache access. Asserting A20M# emulates the 1M-byte address wraparound that occurs on the 8086. A20 masking should not be done by external logic. The A20M# input is ignored during the following three conditions:</p> <ul style="list-style-type: none"> • While paging is enabled • While writing back dirty cache data to system memory. (This occurs only when data is loaded into the cache and A20M# is inactive.) • During system management address space accesses. <p>A20M# is internally connected to a pullup resistor to prevent it from floating active when left unconnected.</p>
BE3# F17 34 BE2# J15 33 BE1# J16 32 BE0# K15 31	<p>Byte Enables BE3#–BE0# (active low). These 3-state outputs determine which bytes within the 32-bit data bus are transferred during a memory or I/O access. During the first cycle of a cache line fill, the microprocessor expects data to be returned as if all data bytes are enabled regardless of the state of the byte enable outputs. BE3#–BE0# float during bus hold states.</p>
BLAST# R16 204	<p>Burst Last (active low). This output indicates that the current 32-bit data transfer is either the last transfer of a multiple transfer cycle or a single transfer cycle. BLAST# is valid for the second and subsequent clock cycles within both burstable and nonburstable cycles. BLAST# floats during bus hold states.</p>
BOFF# D17 6	<p>Back Off (active low). This input forces the microprocessor to abort the current bus cycle and relinquish control of the CPU local bus in the next clock. When asserted, the microprocessor enters the bus hold state but the HLDA output is not asserted. The bus hold state persists until BOFF# is deasserted. Once BOFF# is deasserted, the aborted bus cycle is restarted. While BOFF# is asserted, the microprocessor ignores any data returned.</p> <p>BOFF# is internally connected to a pullup resistor to prevent it from floating active when left unconnected.</p>
BRDY# H15 5	<p>Burst Ready (active low). This input is generated by the system hardware to indicate that the current transfer within a bus cycle can be terminated. The microprocessor samples BRDY# in the second and subsequent clocks of a multiple transfer cycle. If BRDY# is returned instead of RDY# for the first transfer of a multiple transfer cycle, the microprocessor completes the remaining transfers as a burst cycle. BRDY# must be returned instead of RDY# for each transfer except the final transfer to maintain the burst cycle. If RDY# is returned simultaneously with BRDY#, BRDY# is ignored and the burst cycle is aborted. BRDY# is active during address hold states.</p> <p>The microprocessor is capable of bursting code fetches, memory data reads, memory data writes (also with BS16# or BS8# active), or cache line write-back cycles if the BWRT bit in CCR2 is set. The microprocessor bursts cache write-back cycles resulting from a cache inquiry only when all four doublewords within the cache line have been modified and need to be written back. When less than three doublewords are modified, the microprocessor issues the write-back cycles as nonburst 32-bit write cycles.</p> <p>BRDY# is internally connected to a pullup resistor to prevent it from floating active when left unconnected.</p>
BREQ Q15 30	<p>Bus Request (active high). This output is asserted when a bus cycle is pending internally. BREQ is asserted in the first clock of a bus cycle as well as during bus hold and address hold states if a bus cycle is pending. If no other bus cycles are pending, BREQ is deasserted prior to termination of the current cycle.</p>
BS16# C17 7 BS8# D16 8	<p>Bus Size 16 and Bus Size 8 (active low). These inputs allow connection of the 32-bit microprocessor data bus to an external bus of either 16 or 8 bits. When these inputs are asserted, the microprocessor performs multiple bus cycles to complete a single 32-bit transfer. BS16# and BS8# are sampled each clock. The state of these pins during the clock before RDY# goes low is used to determine the bus size for the current cycle. If both BS8# and BS16# are asserted, BS8# is used. During write cycles, valid data is driven only on the data pins corresponding to the active byte enables.</p> <p>BS16# and BS8# are each connected internally to a pullup resistor to prevent them from floating active when left unconnected.</p>

TERMINAL NAME	NO.		DESCRIPTION
	168-PIN	208-PIN	
CLK	C3	24	Clock Input (active high). This input signal is the basic timing reference for the TI486DX4 microprocessors. This signal is also used as an input to time the microprocessor, but the signal is first tripled within the TI486DX4 to provide an internal 3X CPU clock. The CLK signal controls external CPU bus timing. The rising edge of the CLK signal defines the starting point for measurement of external ac specifications for the microprocessor.
D/C#	M15	39	Data Control. This 3-state, bus-cycle-definition signal distinguishes between data and control operations. When high, this signal indicates that the current bus cycle is a data transfer to or from memory. When low, D/C# indicates that the current bus cycle involves a control function such as a halt, interrupt acknowledge, or code fetch.
D0	P1	144	Data Bus (active high). The data bus (D31–D0) signals are 3-state bidirectional signals that provide the data path between the microprocessor and external memory and I/O devices. The data bus inputs data during memory read, I/O read, and interrupt-acknowledge cycles and outputs data during memory and I/O write cycles. Data read operations require that specified data setup and hold times be met for correct operation. The data bus signals float while the CPU is in a hold-acknowledge state.

DP3	A5	90	Data Parity bus (active high). The data parity bus signals are four 3-state bidirectional signals that provide the parity associated with the four-byte data bus. There is one data parity bit for each data byte. Even parity is driven on the data parity bus for all data write cycles. During read cycles, the data parity bus is read by the microprocessor and is used with the corresponding data bus byte to check for even parity.

TERMINAL NAME NO. 168-PIN 208-PIN	DESCRIPTION
EADS# B17 46	<p>External Address Strobe (active low). This input indicates that a valid cache inquiry address is being driven on the address bus (A31–2). The microprocessor checks the on-chip cache for this address. If the cache is operating in write-through mode and has no dirty-bit location, the cache line corresponding to the specified address is invalidated if it is present. If the cache is operating in write-back mode or contains dirty data from a previous write-back operation, the cache line corresponding to the specified address is checked for dirty data. If dirty data exists, the dirty data is written to external memory. The state of the INVAL pin at the time EADS# is sampled active determines the final state of the cache line.</p> <p>A cache inquiry cycle using EADS# may be run with the microprocessor in either an address hold or bus hold state and the inquiry address driven by an external device. Additionally, an inquiry cycle can be run while the microprocessor is driving the address bus. In this case, the current address is used as the inquiry address.</p> <p>EADS# is internally connected to a pullup resistor to prevent it from floating active when left unconnected.</p>
FERR# C14 66	<p>Floating-Point Error (active low). This output is asserted when an unmasked floating point error occurs. FERR# is asserted during execution of the FPU instruction that caused the error. FERR# does not float during bus hold states.</p>
FLUSH# C15 49	<p>Cache Flush (active low). This input invalidates (flushes) the entire cache while in write-through cache mode. If the cache is operating in write-back mode, FLUSH# forces the microprocessor to write back all dirty data in the cache. If the INVAL pin is asserted when FLUSH# is sampled, the microprocessor invalidates the cache contents following the write back of dirty data. FLUSH# needs to be asserted only for a single clock period but must meet specified setup and hold times to ensure recognition at a particular clock edge.</p> <p>FLUSH# is internally connected to a pullup resistor to prevent it from floating active when left unconnected.</p>
HITM# R17 96	<p>Hit on Modified Data (active low). This output indicates that the current cache inquiry address has been found in the cache and that dirty data exists in the cache line. HITM# is asserted one clock after EADS# is sampled active and remains asserted until all dirty data has been written to external memory. The microprocessor does not accept additional cache inquiry cycles while HITM# is asserted. HITM# is disabled (floats) following RESET and is enabled by setting the WBAK bit in CCR2.</p>
HLDA P15 26	<p>Hold Acknowledge (active high). This output indicates that the microprocessor is in a hold-acknowledge state and has relinquished control of its local bus. While in the hold-acknowledge state, the microprocessor drives HLDA active. The microprocessor simultaneously drives the bus and deactivates HLDA when the HOLD request is driven inactive.</p>
HOLD E15 16	<p>Hold Request (active high). This input indicates that another bus master requests control of the local bus. After recognizing the HOLD request and completing the current bus cycle, burst cycle, cache line fill, sequence of locked bus cycles, or cache line write back, the microprocessor responds by floating the local bus and asserting the hold acknowledge (HLDA) output. Once HLDA is asserted, the bus remains granted to the requesting bus master until HOLD becomes inactive. When the microprocessor recognizes HOLD is inactive, it simultaneously drives the local bus and drives HLDA inactive.</p>

Terminal Functions (continued)

TERMINAL NAME	NO.		DESCRIPTION
	168-PIN	208-PIN	
IGNNE#	A15	72	<p>Ignore Numeric Error (active low). This input forces the microprocessor to ignore any pending unmasked FPU errors and allows continued execution of floating point instructions. When IGNNE# is not asserted and an unmasked FPU error is pending, only the following floating point instructions can be executed:</p> <p style="padding-left: 40px;">FNCLEX, FNINIT, FNSAVE, FNSTCW, FNSTENV, and FNSTSW.</p> <p>IGNNE# is ignored when the NE bit in CR0 is set to a 1.</p> <p>IGNNE# is internally connected to a pullup resistor to prevent it from floating active when left unconnected.</p>
INTR	A16	50	<p>Maskable Interrupt Request (positive transition). This level-sensitive input causes the processor to suspend execution of the current instruction stream and begin execution of an interrupt service routine. The INTR input can be masked (ignored) through the Flag Word register IF bit. When unmasked, the microprocessor responds to the INTR input by issuing two locked interrupt-acknowledge cycles. During the second interrupt acknowledge cycle, the microprocessor reads an 8-bit value, the interrupt vector from an external interrupt controller. The 8-bit interrupt vector indicates the interrupt level that caused generation of the INTR and is used by the CPU to determine the beginning address of the interrupt service routine. To assure recognition of the INTR request, INTR must remain active until the start of the first interrupt-acknowledge cycle.</p>
INVAL	S4	67	<p>Invalidate Request (active high). This input can be driven by the system during a cache inquiry cycle to indicate the final state of the cache line if an inquiry hit occurs. INVAL is sampled with EADS# and is required only when operating the on-chip cache in write-back mode. Assertion of INVAL indicates that the final state of the cache line is invalid. Deassertion indicates that the final state of the cache line is valid and clean. The state of the INVAL input is also sampled with the FLUSH# input to determine the final state of the entire cache. INVAL is ignored following RESET and is enabled by setting the WBAK bit in CCR2.</p> <p>INVAL is internally connected to a pullup resistor to prevent it from floating active when left unconnected.</p>
KEN#	F15	13	<p>Cache Enable (active low). This input indicates that the data being returned during the current cycle is cacheable. When KEN# is active one clock before the first BRDY# or RDY# and the microprocessor is performing a cacheable code fetch or memory data read cycle, the cycle is transformed into a 16-byte cache line fill. Returning KEN# active one clock before ready is returned during the last read in the cache line fill causes the line to be written to the on-chip cache. I/O accesses, locked reads, SMM address space accesses, and interrupt-acknowledge cycles are never cached.</p> <p>KEN# is internally connected to a pullup resistor to prevent it from floating active when left unconnected.</p>

Terminal Functions (continued)

TERMINAL NAME	NO.		DESCRIPTION
	168-PIN	208-PIN	
LOCK#	N15	207	<p>Lock (active low). This 3-state, bus-cycle-definition signal is asserted to deny access to the CPU bus by other bus masters. The LOCK# signal may be explicitly activated during bus operations by including the lock prefix on certain instructions. LOCK# is always asserted during descriptor and page table updates, interrupt-acknowledge sequences, and when executing the XCHG instruction. The microprocessor does not enter the hold-acknowledge state in response to HOLD while the LOCK# output is active.</p> <p>An external pullup resistor is recommended to ensure negation during hold-acknowledge states.</p>
M/IO#	N16	37	<p>Memory/I/O. This 3-state, bus-cycle-definition signal distinguishes between memory and I/O operations. When high, this signal indicates that the current bus cycle is a memory read or write. When low, M/IO# indicates that the current bus cycle is an I/O read, I/O write, interrupt acknowledge cycle, or a special bus cycle.</p>
NC†	A3 A14 B10 B12 B14 B16 J1	3 11 18 68 127 167 168 194	<p>Make no external connection.</p>
NMI	B15	51	<p>Nonmaskable Interrupt Request. This rising-edge-sensitive input causes the processor to suspend execution of the current instruction stream and begin execution of an NMI interrupt service routine. The NMI interrupt service request cannot be masked by software. Asserting NMI causes an interrupt which internally supplies interrupt vector 2h to the CPU core. External interrupt-acknowledge cycles are not necessary since the NMI interrupt vector is supplied internally.</p>
PCD	J17	41	<p>Page Cache Disable (active high). This output reflects the state of the PCD page attribute bit in the page table entry or the page directory entry. When paging is disabled or during cycles that are not paged, the PCD output is driven low. PCD is masked by the cache disable (CD) bit in CR0 and floats during bus hold states.</p>
PCHK#	Q17	4	<p>Parity Check (active low). This output is used to indicate that a parity error has occurred on a read operation. Parity is checked for all reads except interrupt acknowledge cycles and coprocessor I/O cycles, and it is only checked for valid bytes as indicated by the byte enable outputs and the bus size inputs. PCHK# is valid only during the clock immediately after read data is returned to the microprocessor and is inactive otherwise. Parity errors signaled by a logic low on PCHK# have no effect on processor execution.</p>
PLOCK#	Q16	206	<p>Pseudo Lock (active low). This output is asserted during reads and writes to/from memory that are greater than 32 bits meaning that multiple bus cycles are required to complete the read/write. PLOCK# is asserted during segment descriptor reads (64 bits), cache line fills (128 bits), and noncacheable prefetches (128 bits). The microprocessor does not enter a hold acknowledge state in response to HOLD while PLOCK# is active, except during noncacheable, nonburstable code prefetches. Under these conditions, the microprocessor acknowledges HOLD on bus-cycle boundaries even though PLOCK# is asserted.</p>
PWT	L15	40	<p>Page Write Through (active high). This output reflects the state of the PWT page attribute bit in the page table entry or the page directory entry. When paging is disabled or during cycles that are not paged, the PWT output is driven low. PWT floats during bus hold states.</p>
RDY#	F16	12	<p>Ready (active low). This input is generated by the system hardware to indicate that the current bus cycle can be terminated. During a read cycle, assertion of RDY# indicates that the system hardware has presented valid data to the CPU. When RDY# is sampled active, the microprocessor latches the input data and terminates the cycle. During a write cycle, RDY# assertion indicates that the system hardware has accepted the microprocessor output data. RDY# is active during address hold states.</p> <p>RDY# is internally connected to a pullup resistor to prevent it from floating active when left unconnected.</p>

† Connecting or terminating (high or low) any NC terminal(s) may cause unpredictable results or nonperformance of the microprocessor.

Terminal Functions (continued)

TERMINAL NAME	NO.		DESCRIPTION
	168-PIN	208-PIN	
RESET	C16	48	<p>Reset (active high). When asserted, RESET suspends all operations in progress and places the microprocessor into a reset state. RESET is an asynchronous input but must meet specified setup and hold times to be properly recognized by the microprocessor at a particular clock edge. While RESET is active, only the HOLD input signal is recognized. The microprocessor output signals are initialized to their reset state during the internal reset sequence.</p> <p>Neither RESET nor WM_RST should be asserted during SMM as system hardware may not return to a known state when the SMI handler is not allowed to complete its routine.</p>
RPLSET1 RPLSET0	A13 C12	64 63	<p>Replacement Set 1–0 (active high). These 3-state outputs indicate which set in the cache is currently undergoing a line replacement. The RPLSET1–0 outputs are disabled (floated) following reset and can be enabled using the RPL bit in the CCR1 Configuration Control register.</p>
RPLVAL#	C13	70	<p>Replacement Set Valid (active low). This three-state output is asserted during a cache line fill cycle indicating that RPLSET1–0 are valid for the current cycle. This output and the RPLSET1–0 outputs are provided so that external hardware can implement the capability for monitoring the cache LRU replacement algorithm. The RPLVAL output is disabled (floated) following reset and can be enabled using the RPL bit in the CCR1 Configuration Control register.</p>
SMADS#	C10	59	<p>SMM Address Strobe (active low). SMADS#, a three-state output, is asserted instead of the ADS# during SMM bus cycles and indicates that SMM memory is being accessed. SMADS# floats while the CPU is in a hold-acknowledge or float state. The SMADS# output is disabled (floated) following reset and can be enabled using the SMI bit in the CCR1 Configuration Control register.</p> <p>When bit 3 of CCR3 is set, this signal becomes SMIACT#, which indicates that SMI is active.</p>
SMI#	A12	65	<p>System Management Interrupt (active low). This 3-state, bidirectional, level-sensitive, input/output signal is an interrupt with higher priority than the NMI interrupt. SMI# must be active for at least one clock period to be recognized by the microprocessor. After the SMI is acknowledged, the SMI# pin is driven low by the microprocessor for the duration of the SMI service routine. The SMI# input is ignored following reset and can be enabled using the SMI bit in the CCR1 Configuration register.</p> <p>When bit 3 of CCR3 is set, this signal becomes an input only.</p> <p>An external pullup resistor is recommended to ensure negation during hold-acknowledge states.</p>
SUSP#	G15	73	<p>Suspend Request (active low). This input requests the microprocessor to enter suspend mode. After recognizing SUSP# active, the processor completes execution of the current instruction, any pending decoded instructions, and associated bus cycles. During suspend mode, internal clocks are stopped. With SUSPA# asserted, the external CLK input can be stopped in either phase. Stopping the CLK input reduces power consumption.</p> <p>To resume operation, the CLK input is restarted (if stopped), followed by deasserting the SUSP# input. The microprocessor resumes instruction fetching and begins execution in the instruction stream at the point it stopped. SUSP# is a level-sensitive input but must meet specified setup and hold times to be properly recognized by the microprocessor at a particular clock edge. The SUSP# input is ignored following reset and can be enabled by setting the SUSP bit in the CCR2 Configuration Control register.</p> <p>SUSP# is internally connected to a pullup resistor to prevent it from floating active when left unconnected.</p>
SUSPA#	A10	71	<p>Suspend Acknowledge (active low). This output indicates that the microprocessor has entered the low-power suspend mode as a result of SUSP# assertion or execution of a HLT instruction. SUSPA# remains asserted until SUSP# is deasserted or until an interrupt is serviced if suspend mode was entered from a HLT instruction. The CLK input can be stopped after SUSPA# has been asserted to reduce power consumption. The SUSPA# output is disabled (floated) after reset and can be enabled by setting the SUSP bit in the CCR2 Configuration Control register.</p>

WM_RST	B13	58	Warm Reset (active high). When asserted, WM_RST suspends all operations in progress and places the microprocessor into a reset state. WM_RST is an asynchronous input but must meet specified setup and hold times to be properly recognized by the microprocessor at a particular clock edge. WM_RST differs from RESET in that the valid and dirty bits in the on-chip cache and the system control bits in the Configuration registers remain unchanged.
			When RESET and WM_RST are asserted simultaneously, WM_RST is ignored and RESET takes priority. WM_RST is ignored following RESET but can be enabled using the WBAK bit in CCR2. WM_RST has the same timing and duration specifications as RESET.
			Neither RESET nor WM_RST should be asserted during SMM as system hardware may not return to a known state when the SMI handler is not allowed to complete its routine.
			WM_RST is internally connected to a pulldown resistor to prevent it from floating active when left unconnected.
W/R#	N17	27	Write/Read. This 3-state, bus-cycle-definition signal is low during read cycles (data is read from memory, I/O, or interrupt acknowledge cycle) and is high during write bus cycles (data is written to memory, I/O, or a special bus cycle).

execution pipeline

The execution path in the TI486DX4 microprocessor consists of five pipelined stages optimized for minimal instruction-cycle times. These five stages are:

- Code fetch
- Instruction decode
- Microcode ROM access
- Execution
- Memory/register file write-back

These stages have hardware interlocks that permit execution overlap for successive instructions.

The 16-byte instruction-prefetch queue fetches code in advance and prepares it for decode, helping to minimize overall execution time. The instruction decoder then decodes four bytes of instructions per clock, eliminating the need for a queue of decoded instructions. Sequential instructions are decoded quickly and provided to the microcode. Nonsequential operations do not have to wait for a queue of decoded instructions to be flushed and refilled before execution continues. As a result, both sequential and nonsequential instruction execution times are minimized.

The execution stage uses a RISC-like, single-cycle execution unit and a 16-bit hardware multiplier. The write-back stage provides single-cycle, 32-bit access to the on-chip cache and posts all writes to the cache and system bus using a two-deep write buffer. Posted writes allow the execution unit to proceed with program execution while the bus-interface unit completes the write cycle.

on-chip write-back cache

The on-chip cache is an 8K-byte unified instruction and data cache implemented using a four-way set associative architecture and a least recently used (LRU) replacement algorithm. The cache is designed for optimum performance in write-back mode; however, the cache can be operated in write-through mode. The cache line size is 16 bytes and new lines are allocated only during memory read cycles. Valid status is maintained on a 16-byte cache line basis, but modified or dirty status for write-back mode is maintained on a 4-byte (double-word) basis. Therefore, only the double words that have been modified are written back to external memory when a line is replaced in the cache. The CPU can access the cache in a single internal clock cycle for both reads and writes.

The TI486DX4 on-chip cache can be configured to run in write-through or in write-back mode. By using the write-back cache configuration, performance increases due to a reduction in the number of external memory write cycles. The write-back mode optimizes performance of the CPU core as external memory writes are required only when a cache miss occurs, a modified line is replaced in the cache, or an external bus master requires access to the data. The write-back architecture is especially effective in improving performance of the TI486DX4 devices.

Write-through cache architectures require that all writes to the cache simultaneously update external memory. These updates are unnecessary as long as the cache contains the updated instruction/data necessary to perform the operations. The write-back architecture allows the data to be written to the cache without updating external memory, thereby eliminating unnecessary external writes that can reduce system performance.

floating-point unit (FPU) operations

The TI486DX4 FPU high-performance coprocessor is an integrated part of the microprocessor, thereby eliminating the overhead associated with an external math coprocessor. When the FPU is not in use it is automatically powered down to reduce power consumption. The external system is supported by two terminals, FERR# and IGNNE#. FERR# output reports that an unmasked floating point error has occurred. The input IGNNE# is provided so that the system can signal the processor to ignore numeric error.

clock-tripling

The TI486DX4 microprocessor is designed with an on-chip clock-tripler feature. Upon power-up, the microprocessor's internal core operates at three times the input clock frequency, while the external bus interface remains the same as the input clock frequency. This increases the speed of the on-chip cache, FPU, instruction decode, and instruction execution while the external interface remains the same.

In addition to the clock-tripler feature, the TI486DX4 microprocessor supports stopping the CLK input.

power management

The TI486DX4 microprocessors incorporate advanced power-management features such as suspend mode, static operation, and operation at 3.45 V. These capabilities are attractive for battery-powered notebook and energy-efficient desktop PC systems.

system-management mode (SMM)

System-management mode (SMM) provides an additional interrupt and a separate address space that can be used for system power management or software-transparent emulation of I/O peripherals. SMM is entered using the system-management interrupt (SMI#) input or the SMINT instruction. SMI# has a higher priority than any other interrupt. While running in SMM address space, the SMI interrupt routine can execute without interfering with the operating system or application programs.

After receiving an SMI# interrupt, portions of the CPU state are automatically saved, SMM is entered, and program execution begins at the base of SMM address space. The location and size of the SMM memory is programmable in the TI486DX4 microprocessors. Eight SMM instructions have been added to the 486 instruction set that permit software entry into SMM and saving and restoring the total CPU state when in SMM mode.

suspend mode and static operation

The power-management feature in the TI486DX4 microprocessors allows a dramatic reduction in the current required when the microprocessor is in suspend mode (typically using less than one percent of the operating current). Suspend mode is entered either by a hardware- or software-initiated action. Using hardware to initiate suspend mode involves a two-pin handshake using the SUSP# and SUSPA# signals.

The software initiates suspend mode with execution of the HLT instruction. Once the microprocessor is in suspend mode, power consumption can be reduced further by stopping the external clock input. The resulting current draw is typically 500 μ A.

Since these microprocessors are static devices, no internal CPU data is lost when the clock input is stopped.

mixed 3.45-V and 5-V operation

The TI486DX4 devices operate from a 3.45-V supply. The microprocessors feature 5-V-tolerant inputs and outputs meaning that they can be incorporated in system designs that use both 3.45-V and 5-V devices.

electrical specifications

Electrical specifications include electrical connection requirements for all package pins, maximum ratings, recommended operating conditions, dc electrical characteristics, and ac characteristics.

electrical connections

Requirements are given for power and ground connections, decoupling, termination of inputs with internal pullup/pulldown resistors, termination of system functional inputs requiring external pullup resistors, termination of unused inputs, and connection to terminals designated NC.

power and ground connections and decoupling

The TI486DX4 microprocessors must be installed and tested using standard high-frequency techniques. The high clock frequencies used in the microprocessors and their output buffer circuits can cause transient power surges when several output buffers switch output levels simultaneously. These effects can be minimized by filtering the dc power leads with low-inductance decoupling capacitors, by using low-impedance wiring, and by making connection to all of the V_{CC} and V_{SS} (GND) terminals.

pullup/pulldown resistors

Table 5 lists the terminals that are internally connected to pullup or pulldown resistors. The pullup resistors are connected to V_{CC} and the pulldown resistors are connected to V_{SS} . When unused, these inputs do not require connection to external pullup or pulldown resistors. The SUSP# terminal is unique because it is connected to a pullup resistor only when it is not asserted.

The internal pullup and pulldown resistors are designed to tie-off the individual internal signal associated with that pin. External signals should not be terminated to any of these pins.

Table 5. Terminals Connected to Internal Pullup and Pulldown Resistors

SIGNAL	168-TERMINAL	208-TERMINAL	RESISTOR
A20M#	D15	47	Pullup
AHOLD	A17	17	Pulldown
BOFF#	D17	6	Pullup
BS16#	C17	7	Pullup
BS8#	D16	8	Pullup
BRDY#	H15	5	Pullup
EADS#	B17	46	Pullup
FLUSH#	C15	49	Pullup
IGNNE#	A15	72	Pullup
INVAL	S4	67	Pullup
KEN#	F15	13	Pullup
RDY#	F16	12	Pullup
UP#†	C11	194	Pullup
SUSP#	G15	73	Pullup
WM_RST	B13	58	Pulldown

† 168-pin CPGA only

TI recommends that the ADS#, LOCK#, and SMI# output terminals be connected to pullup resistors, as indicated in Table 6. The external pullups ensure that the signals remain deasserted during hold-acknowledge states.

Table 6. Terminals Requiring External Pullup Resistors

SIGNAL	168-TERMINAL	208-TERMINAL	EXTERNAL RESISTOR
ADS#	S17	203	20-k Ω pullup
LOCK#	N15	207	20-k Ω pullup
SMI#	A12	65	20-k Ω pullup

NC designated terminals

Terminals designated NC must be left disconnected. Connecting or terminating any NC terminal(s) to a pullup resistor, pulldown resistor, or an active signal can cause unpredictable results or nonperformance of the microprocessor.

unused signal input terminals

All signal inputs not used by the system designer and not listed in Table 5 should be connected either to V_{SS} or to V_{CC} . Connect active-high inputs to V_{SS} through a 20-k Ω ($\pm 10\%$) pulldown resistor and active-low inputs to V_{CC} through a 20-k Ω ($\pm 10\%$) pullup resistor to prevent possible spurious operation.

absolute maximum ratings over operating case temperature range (unless otherwise noted)†

Supply voltage, V_{CC}	−0.5 to 4 V
Voltage on any terminal	−0.5 to 6 V
Input clamp current, I_{IK}	10 mA
Output clamp current, I_{OK}	25 mA
Case temperature, T_C	−65°C to 110°C
Storage temperature, T_{stg}	−65°C to 150°C

† Stresses beyond those listed under absolute maximum ratings may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under recommended operating conditions is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

recommended operating conditions

		MIN	MAX	UNIT
V_{CC}	Supply voltage	With respect to V_{SS}		V
V_{IH}	High-level input voltage	2	5.5	V
V_{IL}	Low-level input voltage	−0.3	0.6	V
I_{OH}	High-level output current	$V_{OH} = V_{OH}(\min)$		mA
I_{OL}	Low-level output current	$V_{OL} = V_{OL}(\max)$		mA
T_C	Case temperature	Power applied	GA 168-pin PGA	0 75
			WR 208-pin QFP	0 75
				°C

electrical characteristics at recommended operating conditions

PARAMETER	TEST CONDITIONS	168-PIN PACKAGE			208-PIN PACKAGE			UNIT	
		MIN	TYP†	MAX	MIN	TYP†	MAX		
V_{OL}	Low-level output voltage	$I_{OL} = 3 \text{ mA}$			0.45			V	
V_{OH}	High-level output voltage	$I_{OH} = -1 \text{ mA}$			2.4			V	
I_I	Input current (leakage)	$V_{IN} = 0, V_{IN} \geq V_{CC}$, See Note 1			± 15			μA	
I_{IH}	High-level input current	$V_{IH} = 2.4 \text{ V}$, See Note 2			200			μA	
I_{IL}	Low-level input current	$V_{IL} = 0.45 \text{ V}$, See Note 1			-400			μA	
I_{CC}	Supply current (active mode)	Internal CLK = 100 MHz, See Note 3			400	800	400	800	mA
I_{CCSM}	Supply current (suspend mode)	Internal CLK = 100 MHz, See Notes 3 and 4			20	100	20	100	mA
I_{CCSS}	Supply current (standby)	0 MHz, Suspended, CLK stopped, See Note 5			0.5	15	0.5	1	mA
C_i	Input capacitance	$f = 1 \text{ MHz}$, See Note 5						pF	
C_o	Output or I/O capacitance	$f = 1 \text{ MHz}$, See Note 6			20			pF	
C_{clk}	Clock input capacitance	$f = 1 \text{ MHz}$, See Note 6			20			pF	

† Typical values are at $V_{CC} = 3.45 \text{ V}$ and $T_A = 25^\circ\text{C}$.

- NOTES:
1. Applicable for all input terminals except those with an internal pullup resistor. See Table 5.
 2. Applicable for all inputs (except WM_RST) that have an internal pulldown resistor. See Table 5. WM_RST maximum $V_{IH} = 500 \mu\text{A}$.
 3. Refers to the internal frequency
 4. All inputs at 0.4 V or $V_{CC} - 0.4$. All inputs held static, (except CLK as indicated). All outputs unloaded (static $I_{OUT} = 0$). Valid for UP# = 0 (168-pin CPGA only).
 5. All inputs at 0.4 V or $V_{CC} - 0.4$. All inputs held static,. All outputs unloaded (static $I_{OUT} = 0$).
 6. Not 100% tested

switching characteristics

The switching characteristics provide detailed information regarding measurement points, specific timing requirements for setup and hold times, and propagation delay times of the TI486DX4 microprocessors.

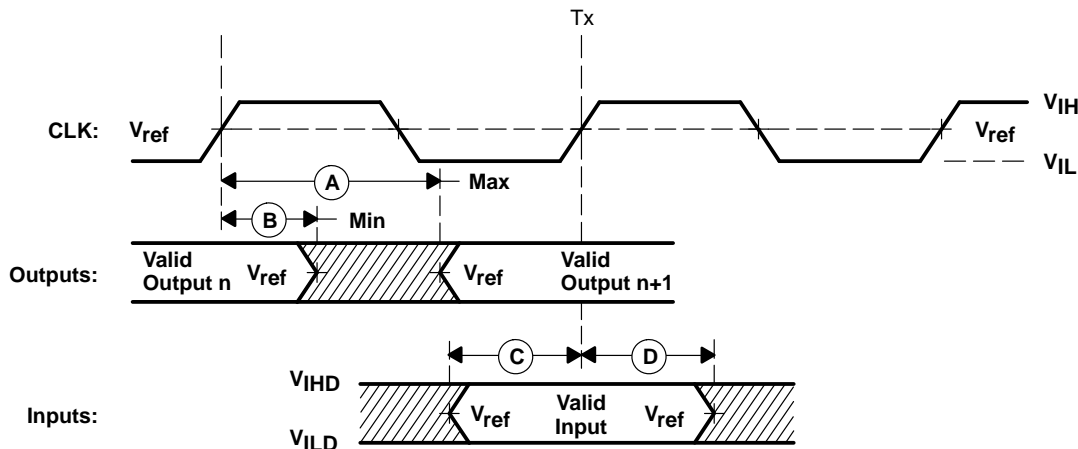

measurement points for switching characteristics

The rising-clock-edge reference level, V_{ref} , and other reference levels are specified in Table 7. Input or output signals must cross these levels during testing.

Table 7. Measurement Levels for Switching Characteristics

SYMBOL	MEASUREMENT LEVEL	UNIT
V_{ref}	1.5	V
V_{IHD}	2.3	V
V_{ILD}	0	V

Figure 3 shows delays (A and B) and input setup and hold times (C and D). Input setup and hold times are specified minimums, defining the smallest acceptable sampling window during which a synchronous input signal must be stable for correct operation.

LEGEND: A – Maximum Output Delay Specification
 B – Minimum Output Delay Specification
 C – Minimum Input Setup Specification
 D – Minimum Input Hold Specification

- NOTES: 7. Input clock can be stopped; therefore, minimum CLK frequency is 0 MHz.
8. These parameters are not tested. They are determined by design characterization.
9. Float condition occurs when maximum output current becomes less than I_L in magnitude. Float is not 100% tested.
10. Not 100% tested.
11. These inputs are allowed to be asynchronous to CLK. The setup and hold specifications are given for testing purposes, to assure recognition within a specific CLK period.

switching waveforms

Switching waveforms for the TI486DX4 microprocessor are illustrated in Figure 4 through Figure 8.

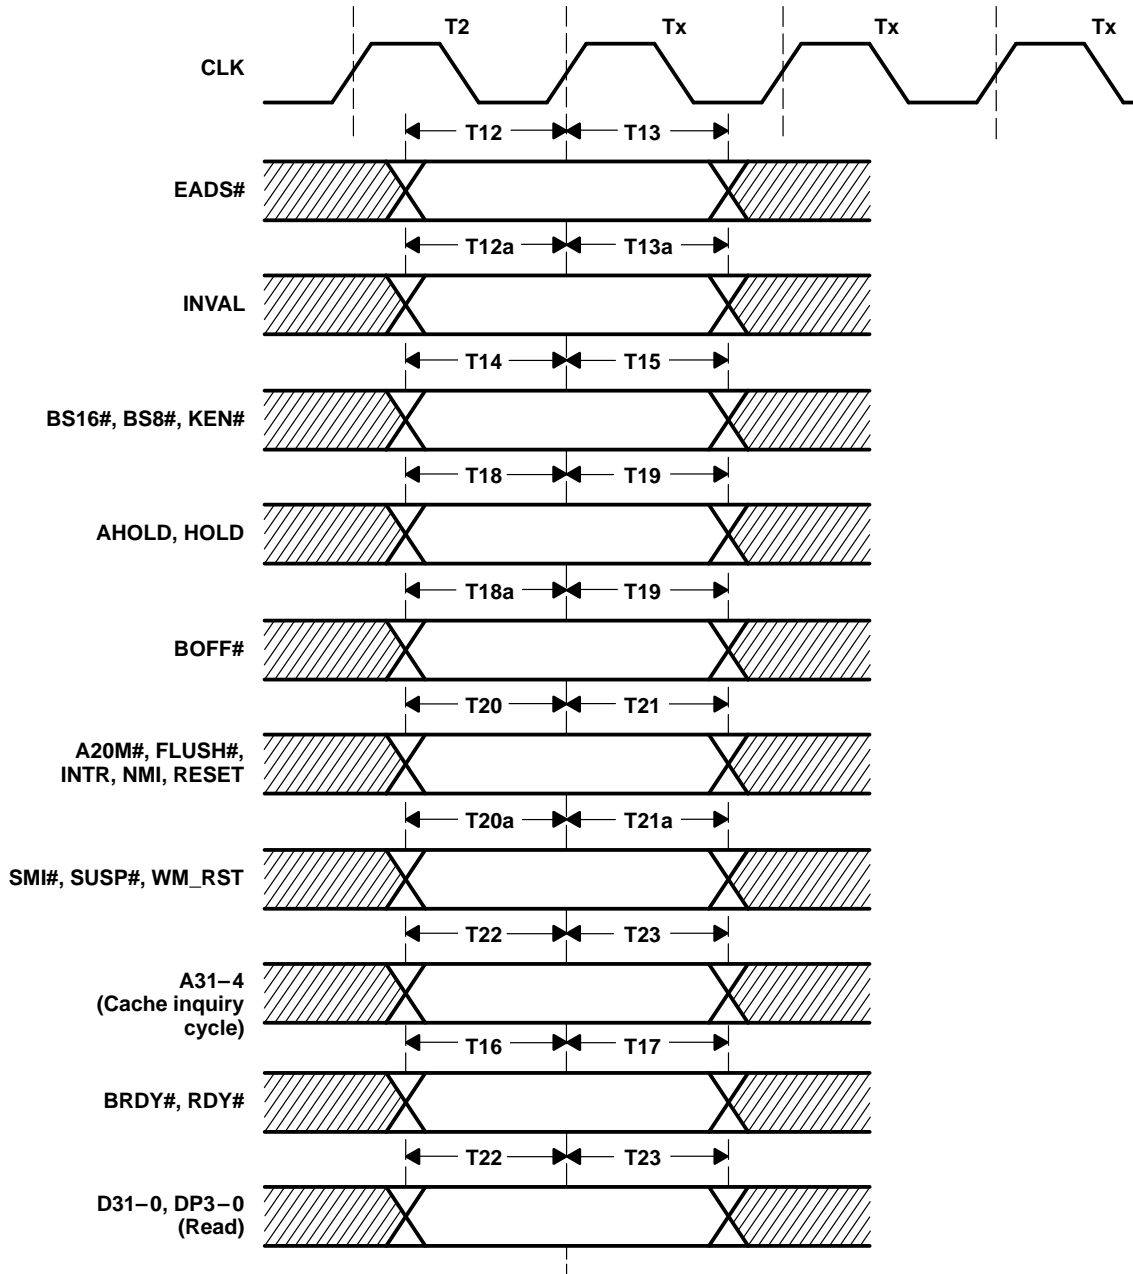

Figure 8. Input Signal Setup and Hold Timing

thermal characteristics

The junction-to-ambient (typical) values vary for individual applications depending on factors relating to how the device is mounted and the surrounding environment such as:

- Circuit trace density of the printed circuit board (PCB) and/or the presence or absence of ground or power planes internal to the PCB that affect the ability of the board to conduct heat away from the device
- Whether the device is soldered to the PCB or is inserted into a socket
- Orientation of the PCB on which device is mounted and the proximity of adjacent PCBs or system enclosure features that impede natural convection air circulation around the device
- Ambient-air temperature in close proximity to the device and the proximity of other high-power devices in the system

The final responsibility for verifying designs incorporating any version of a TI microprocessor rests with the customer originating the design. Recommended case temperature extremes are specified in recommended operating conditions. Thermal resistances at various airflows are shown in Table 8 and Table 9.

Table 8. 168-Pin CPGA Thermal Resistance and Airflow

AIRFLOW (FT/MIN)	THERMAL RESISTANCE (°C/W)	
	168-PIN CERAMIC PGA PACKAGE	
	R _{θJC}	R _{θJA}
0	3	19
100	3	16
200	3	14
400	3	11
600	3	10

Thermal resistance values shown are based on measurements made on similar ceramic PGA packages.

Table 9. 208-Pin CQFP Thermal Resistance and Airflow

AIRFLOW (FT/MIN)	THERMAL RESISTANCE (°C/W)	
	208-PIN CERAMIC QUAD FLAT PACKAGE	
	R _{θJC}	R _{θJA}
0	4	29
100	4	25
200	4	22
400	4	19
600	4	16

Thermal resistance values shown are based on measurements made on similar ceramic PGA packages.

airflow measurement setup

The wind tunnel used for airflow measurements is represented schematically in Figure 9.

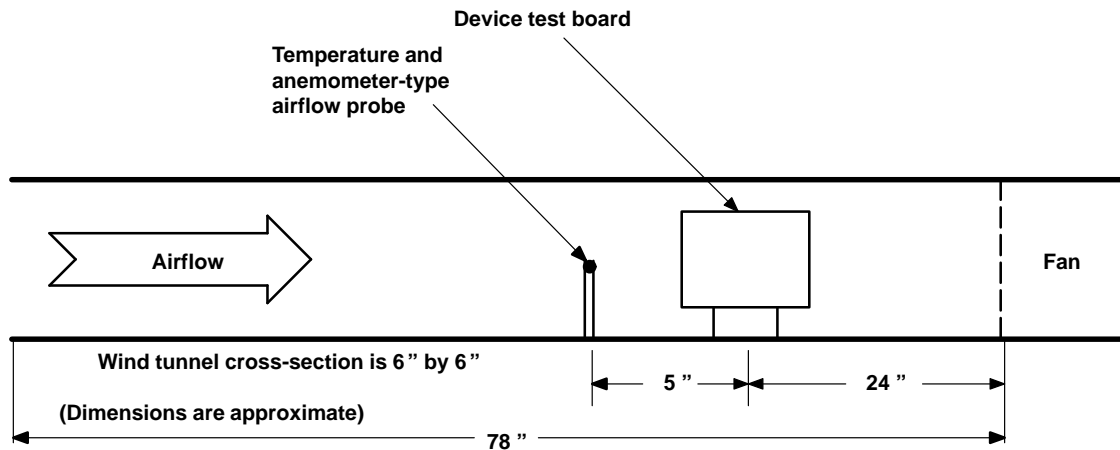

Figure 9. Wind Tunnel Schematic Diagram

Typically, the devices undergoing thermal test are mounted on a test board consisting of 0.062-inch thick FR4 printed circuit board material with one-ounce copper etch. Surface-mount devices are soldered to the test board using matching footprints with the minimal circuit-trace density required to electrically interconnect the device to the board. PGA devices are typically inserted in a socket that is soldered to the test board.

thermal parameter definitions

The maximum average junction temperature (T_{Jmax}) and the maximum ambient temperature (T_{Amax}) can be calculated using the following equations:

$$T_{Jmax} = T_C + (P_{max} \times R_{\theta JC})$$

$$T_{Amax} = T_J - (P_{max} \times R_{\theta JA})$$

where:

- T_{Jmax} = Maximum average junction temperature (°C)
- T_C = Case temperature at top center of package (°C)
- P_{max} = Maximum device power dissipation (W)
- $R_{\theta JC}$ = Junction-to-case thermal resistance (°C/W)
- T_{Amax} = Maximum ambient temperature (°C)
- T_J = Average junction temperature (°C)
- $R_{\theta JA}$ = Junction-to-ambient thermal resistance (°C/W)

Values for $R_{\theta JA}$ and $R_{\theta JC}$ are given in Table 8 for various airflows.

mechanical specifications

The TI486DX4 microprocessor is supplied in the following packages:

- 168-pin, ceramic pin grid array package
- 208-pin, ceramic quad flat package

Mechanical specifications provide physical dimensions for the 168-pin and 208-pin packages.

Industry-standard dimensioned drawings are supplied for each package.

IMPORTANT NOTICE

Texas Instruments (TI) reserves the right to make changes to its products or to discontinue any semiconductor product or service without notice, and advises its customers to obtain the latest version of relevant information to verify, before placing orders, that the information being relied on is current.

TI warrants performance of its semiconductor products and related software to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

Certain applications using semiconductor products may involve potential risks of death, personal injury, or severe property or environmental damage ("Critical Applications").

TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, INTENDED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT APPLICATIONS, DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS.

Inclusion of TI products in such applications is understood to be fully at the risk of the customer. Use of TI products in such applications requires the written approval of an appropriate TI officer. Questions concerning potential risk applications should be directed to TI through a local SC sales office.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards should be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance, customer product design, software performance, or infringement of patents or services described herein. Nor does TI warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used.
